Connection guide

Every dashboard starts from the published tables, so every report shows the same numbers.

1. The published tables

Table	What it is for
`dim_customer`	Every known customer: first and last purchase, number of purchases, sales, and how they found the business where the customer list says.
`dim_date`	Calendar of every day in the data
`dim_item`	Every item sold, with its group, price and unit cost where the item list gives them; an item missing from the list keeps its code as its name.
`dim_place`	Every site the business trades from, with its size where the site list gives it.
`fact_daily_sales`	Sales, cost and gross profit by day and site, the table most dashboards start from.
`fact_expenses_monthly`	Expenses by month, cost centre and category, as booked in the accounts.
`fact_marketing_daily`	Advertising spend and results by day, channel and campaign.
`fact_sales`	One row per line sold: when, where, what, to whom, for how much, and what it cost.
`fact_staff_monthly`	People, hours and pay by month and site.
`mart_kpi_monthly`	The monthly management view by site: sales, gross profit, running costs where the accounts have them, operating profit and staff hours.

They are refreshed every night in `serving/` as CSV and Parquet files (with `manifest.json`, which says when), and in the warehouse itself.

2. Power BI Desktop (free, Windows)

1. **Get data > Folder**, choose the `serving` folder; or **Get data > Parquet** for one table.
2. Load `fact_daily_sales`, `dim_place`, `dim_item` and `dim_date`; relate them on `place_id`, `item_id` and `day`.
3. Refresh after each night's run. Sharing a report online needs a Power BI Pro licence for each person who views it and a work email address.

3. Looker Studio (free, any computer with a browser)

- With the company's Google account, upload the CSV files to Google Sheets or BigQuery and add them as data sources.
- With the warehouse in BigQuery, connect directly: **Add data > BigQuery**, then choose the dataset.

4. Excel

Data > Get Data > From File > From Text/CSV, choose a file in `serving`, then **Refresh All** after each night.

5. The company's own cloud

1. The company creates the account in its own name, with its own payment card: a Google Cloud project with BigQuery, or a managed PostgreSQL database.
2. It invites ProQuant as a user with the access needed, and removes that access after handover.
3. The create-table script in `deploy/` is run once; the platform's address goes in `.env` on the machine that runs it.
4. Nobody shares a password: each person signs in with their own account.

6. The dashboard that needs no account

`platform_dashboard.html` opens in any browser and needs no account or server; it shows the nights, every batch, the tables and their lineage.
